1.1

Describe the environment state and action spaces, and reward function. Given a state and an action, is the state transition deterministic?

State space: $S \in \{0, 1, 2, \ldots, 15\}$ represents the index from top-left to bottom-right of 4x4 grid. Each state s can be $\{S, F, H, G\}$

where

```
S: starting point, safe
F: frozen surface, safe
H: hole, fall to your doom
G: goal, where the frisbee is located
```

The terminal state is the goal state G and hole state H.

Reward is 0 for every step taken in $\{S, F, H\}$, 1 for reaching the final goal state G.

$$r = 1 \text{ if s = G}$$

$$r = 0 \text{ Otherwise}$$

The state transition is not deterministic, becasue the transition probability of given state and action is not 1.

1.2

Starting with teh defintion of a value function, show that for a deterministic policy $\pi(s)$, the value function $v(s)$ can be expressed as:

$$v(s) = \sum_{s\prime \in S} p(s\prime|s,a)\left[r(s,a,s\prime) + \gamma v(s\prime)\right]$$

Return $G_t = \sum_{\tau=t}^{T} \gamma^{\tau-t} R_\tau$

Assume probabilistic transitions $T(s,a,s\prime) = R(s\prime|a,s)$

Deterministic policy $\pi(s) = a \; \forall a \in A$

$$v(s) = E_\pi\left[G_t|S_t = s\right]$$

$$v(s) = E_\pi[\sum_{k=t}^{\infty} \gamma^{k-t} R_k | s_t = s]$$

$$= E_\pi[R_t + \gamma \sum_{k=t+1}^{\infty} \gamma^{k-t} R_k | s_t = s]$$

$$= \sum_a \pi(a|s) \sum_{s\prime} p(s\prime|a,s)\left[r(s,a,s\prime) + \gamma E_\pi[\sum_{k=t}^{\infty} \gamma^{k-t} R_k | s_{t+1} = s\prime]\right]$$

$$= \sum_a \pi(a|s) \sum_{s\prime} p(s\prime|a,s)\left[r(s,a,s\prime) + \gamma v(s\prime)\right]$$

In our case, $a = \pi(s)$ is a deterministic policy, we can omit the probability of policy in the above equation.

$$v(s) = \sum_{s\prime \in S} p(s\prime|s,a)\left[r(s,a,s\prime) + \gamma v(s\prime)\right]$$

1.3

Write a functionTestPolicy(policy), that returns the average rate of successful episodes over 100 trials for a deterministic policy. What is the success rate of a policy(number of times completed / total number of trials) given by $\pi(s) = (s + 1)$.

In [6]:

```python
def TestPolicy(
    self,
    policy: Callable,
    trials: int = 100,
    render: bool = False,
    verbose: bool = False,
) -> float:
    """
    Test a policy by running it in the given environment.

    :param policy: A policy to run.
    :param env: The environment to run the policy in.
    :param render: Whether to render the environment.

    :returns: success rate over # of trials.
    """
    assert trials > 0 and isinstance(trials, int)

    success = 0
    reward = 0
    for _ in range(trials):
        obs = self.env.reset()
        done = False
        while not done:
            act = policy(obs)
            obs, rew, done, info = self.env.step(act)
            reward += rew
            if render:
                self.env.render()
                time.sleep(0.1)
            if done and obs == 15:
                success += 1
    success_rate = success / trials
    mean_reward = reward / trials
    if verbose:
        print(f"Success rate: {success_rate}")
    return success_rate, mean_reward
```

In [7]:

```python
# 3. Naive policy
policy = lambda s: (s + 1) % 4
naive_success_rates = []
for _ in range(10):
    naive_success_rate, _ = mdp.TestPolicy(policy, render=False)
    naive_success_rates.append(naive_success_rate)
print(f"Average naive_success_rates: {np.mean(naive_success_rates)}")
```

```
Average naive_success_rates: 0.017
```

1.4

Write a functionLearnModel, that returns the transition probabilities $p(s'|a, s)$ andreward function $r(s, a, s')$. Estimate these values over 10^5 random samples.

In [8]:

```python
def learnModel(self, n_samples: int = 10 ** 5) -> Tuple[np.ndarray, np.ndarray]:
    """
    Estimate transition probabilities p(s'|a, s) and
    reward function r(s, a, s') over n_samples random samples.

    :param n_samples: Number of random samples to use.
    :returns: transition probabilities and reward function.
    """
    assert n_samples > 0 and isinstance(n_samples, int)

    # Dimension of observation space and action space (both discrete)
    P = np.zeros((self.nS, self.nA, self.nS))  # transition probability: S x A x S' -> [0, 1]
    R = np.zeros_like(P)  # reward r(s, a, s')

    obs = self.env.reset()
    done = False
    for _ in range(n_samples):
        # Random action
        act = env.action_space.sample()
        nxt_obs, rew, done, _ = self.env.step(act)

        P[obs, act, nxt_obs] += 1
        R[obs, act, nxt_obs] += rew
        obs = nxt_obs

        if done:
            obs = self.env.reset()
    # Normalize transition probabilities -> [0,1]
    p1 = P.copy()  # Don't modify P dircetly
    for s in range(self.nS):
        for a in range(self.nA):
            total_counts = np.sum(P[s, a, :])
            if total_counts != 0:
                p1[s, a, :] /= total_counts
    # Avoid division by zero error
    R /= np.where(P!=0, P, 1)

    # Store the estimated transition probabilities and reward function
    self.P_hat = p1
    self.R_hat = R
    return p1, R
```

In [9]:

```python
p1, r1 = mdp.learnModel(n_samples=10 ** 5)
mse = lambda x, y: np.mean((x - y) ** 2)

MSE_P, MSE_R =  mse(mdp.P, p1), mse(mdp.R, r1)
print(f"Mean square error of P: {MSE_P}, \nMean square error of R: {MSE_R}")
```

```

2.1. Solve the environment using Q-learning over 5000 episodes. For exploration duringtraining, take random actions with probability 1-e/5000 where e is the number ofcurrent episode. Plot the success rate of the learned policy at an interval of 100episodes.

(a) Train the policy using the following learning rates with γ= 0.99.Report what you observe.

A small α tends to work better than

With a larger alpha, the Q Learning will add more weight to the reward to go. However, Q-Learning learn slowly. The Q value is not very good during the early stage of learning. (agent likely not visited every state in the enviroment)

Q value may change dramatically with a large alpha which leard to instability depend on the method. MC is an unbiased estimator of the Q value but high variance. On the other hand, TD(0) is biased but low variance. Takeing a larger step size will let agent learn faster but create more variace on the estimation.

In [15]:

```python
# 7
learning_rate = [0.05, 0.1, 0.25, 0.5]
discount_factor = [0.9, 0.95, 0.99]
    # (a)
for lr in learning_rate:
    pi_QL, Q_pi, success_rates_QL = mdp.QLearning(
        n_episodes=5_000,
        gamma=0.99,
        alpha=lr,
        strategy="epsilon",
        verbose=False,
    )

```

```
-------- Q Learning (alpha=0.05, gamma=0.99, strategy: epsilon) --------:
```

In the previous question, the exploration was linearly annealed. Solve the environmentusing Q-learning by proposing a different strategy to explore. Find a suitable α and γ for your method. Report your strategy and training results.

Best $\alpha = 0.1, \gamma = 0.99$

In [17]:

```python
for lr in learning_rate:
    for g in discount_factor:
        pi_QL, Q_pi, success_rates_QL = mdp.QLearning(
            n_episodes=5_000,
            gamma=g,
            alpha=lr,
            strategy="exponential",  # "epsilon"
            verbose=False,
        )
        simple_plot(
            success_rates_QL,
            xlabel="Iteration",
            ylabel="Success rate",
            title=(
                f"Average rate of success of the learned policy (Q Learning), "
                + r"$\alpha=$"
                + f"{lr}, "
                + r"$\gamma=$"
                + f"{g}"
            ),
            # save_path=plot_dir / f'QL_exp_a_{lr}_r_{g}.png',
            show=True,
        )
        print("\n")
```

A simple Count-based Exploration by using exponential decay:

$$\frac{dN}{dt} = -\lambda N$$

The solution to this equation is:

$$N(t) = N_0 e^{-\lambda t}$$

In this case N_0 is the initial exloration probability at $t = 0$ is 1 and the constaint λ is the decay constant, $\lambda = 0.001$. Therefore, agent will absolutaly explore at $t = 0$ and exponentially decay the exploration probability across time.

This exploration strategy does not work well in hard exploration problem but it is good enough for our environment.

In [18]:

```
prob = []
init_prob = 1
lamd = 0.001
for t in range(5_000):
    Nt = init_prob * np.exp(-lamd * t)
    prob.append(Nt)

plt.plot(prob)
plt.xlabel("Iteration")
plt.ylabel("Probability")
plt.title("Exploreation Probability")
plt.show()
```
